

Supplier Report Processing

Configurable ETL for recurring imports and 1C workflows

Python / pandas / YAML / SQL Server / Excel / JSON

THE PROBLEM

Supplier reports differ in headers, layout, data types and nested row groups. Recurring imports require consistent fields, quality checks and a controlled handoff to downstream systems.

MY ROLE

Created the solution and integrated it into working processes, covering input transformation, quality control, output generation and workflow handoff.

THE SOLUTION

Created and integrated a configurable ETL pipeline that maps supplier fields through YAML rules, converts values, preserves hierarchy boundaries, fills registry metadata and generates template-based Excel output. SQL Server registry reads and JSON status commands connect the stages to a 1C workflow.

Supplier Excel

Map + validate

Template output

1C status handoff

DELIVERABLE

Standardized Excel files for downstream imports, required-field checks and staged JSON status messages. Supplier-specific rules are separated from the reusable processing logic.

VERIFICATION

Eight focused local checks passed on the reviewed copy: six regression tests and two JSON publication tests. Checks cover metadata, hierarchy boundaries, blank required fields, dry-run behavior and template output. Concurrent publication produced one complete file without overwriting an existing result.

SCOPE

Checks use synthetic inputs. Live SQL Server/1C, Windows Excel COM and network-share behavior were not validated. These checks are not production performance benchmarks.
